

# Runtime transparency (?)

or

- ~ “transparent server” (Hal Finney ca 2001)
- ~ Keylime (MIT ca 2016, Redhat, IBM)
- ~ System Transparency (Mullvad 2019)
- ~ Project Oak (Google 2019)
- ~ Apple Private Cloud Compute (Apple 2024)
  - **“verifiable transparency”, “runtime transparency”**
- ... what else?

## Organizations & Core Activities

<b>Organization</b>	<b>Core activities</b>
Amagicom AB	Holding company
– Mullvad VPN AB	<ul style="list-style-type: none"><li>– Mullvad VPN</li><li>– Mullvad Browser</li><li>– Mullvad Leta (search engine)</li></ul>
– Karlstad Internet Privacy Lab AB	<ul style="list-style-type: none"><li>– Traffic analysis defense against AI-based classifiers</li></ul>
– Glasklar Teknik AB	<ul style="list-style-type: none"><li>– System Transparency</li><li>– Sigsum</li><li>– Debian Snapshot service</li></ul>
– Tillitis AB	<ul style="list-style-type: none"><li>– FPGA-based open-source security hardware</li><li>– TKey (a USB security key)</li></ul>

# System Transparency – ([system-transparency.org](http://system-transparency.org))

– a security architecture for transparent systems

Hardware

Software

+ Identity

-----

Identity's Behavior

What must I ~~trust~~ to?  
be vulnerable

- the **hardware** and the **operator** who provisioned it
- the **software** and the **developer** who provided the source code

System  
Transparency  
Authentication  
Mechanism

Fredrik Strömberg

STAM provides  
accountability for  
running systems

# TLS

## (and other secure communication protocols)

- Authentication is done by establishing trust in a certificate.
- The certificate contains an identity and a public key.
- The authenticated key is used to establish secure communication.
- Secure communication can be established assuming the remote system's private key has not been compromised.

# STAM

## (and remote attestation mechanisms)

- Authentication is done by establishing trust in a certificate.
- The certificate contains an identity, a public key, **and other claims about the remote system's attributes.**
- The authenticated key is used to establish secure communication.
- Secure communication can be established assuming the remote system's private key has not been compromised.

hw + sw  $\rightarrow$  behavior

	concept. underst.	human- readable	machine- usable	running system
SW		source code	build artifact	reachable state space
hw		blueprint, Verilog	physical construction	

	concept. underst.	human-readable	machine-usable	running system
SW		<ul style="list-style-type: none"> <li>○ src rel. sig.</li> <li>source code</li> </ul>	<ul style="list-style-type: none"> <li>○ build rel. sig.</li> <li>build artifact</li> </ul>	<ul style="list-style-type: none"> <li>reachable state space</li> </ul>
hw	<ul style="list-style-type: none"> <li>concept. integr.</li> </ul>	<ul style="list-style-type: none"> <li>blueprint, Verilog</li> </ul>	<ul style="list-style-type: none"> <li>physical construction</li> <li>procurement, provisioning</li> </ul>	

concept. integr.

○ src rel. sig.

○ build rel. sig.

○ procurement, provisioning

## **System Transparency – ([system-transparency.org](https://system-transparency.org))**

Builds on:

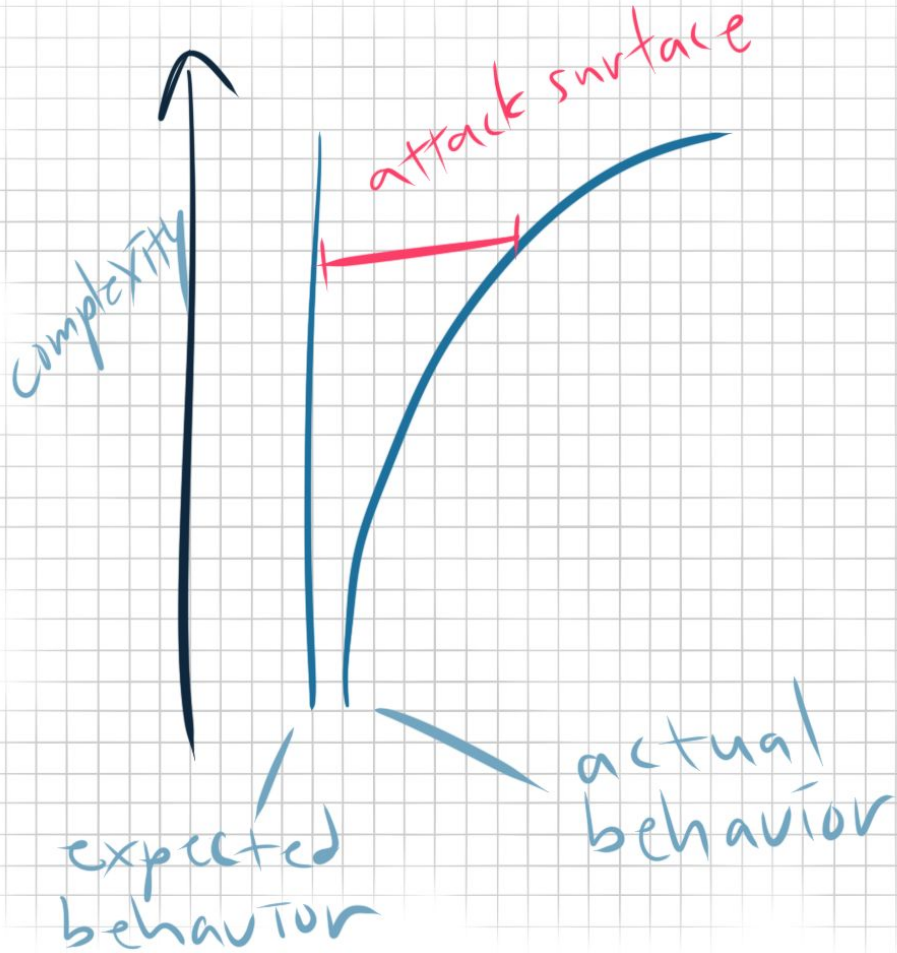

- secure network communication protocols with entity authentication mechanisms
- remote attestation
- reproducible builds
- Sigsum (transparency logging with witness cosigning)

# Complexities that matter

**Computational complexity** is the foundation of modern cryptography.

What would the Internet look like without TLS?

**Conceptual complexity** is the root cause of most(?) security vulnerabilities.

# High-leverage defences

(increase confidence that intended and actual system behaviour are the same)

## 1. Maximise use of cryptographic defences

(as cryptography relies on computational complexity)

## 2. Maximise use of hardware defences

(as hardware defines the rules of software)

## 3. Maximise conceptual integrity

(see quotes)

## 4. Constrain the reachable state space whenever possible

## 5. Distribute trust assumptions

**END**

# STAM

will assure a local system of a remote system's

- platform provenance (signed provisioning manifest)
- platform state (signed TPM measurements)
- software authenticity (signed code)
- source code traceability (signed reproducible builds)
- attestation freshness (measure a recent Sigsum STH)
- certificate transparency (Sigsum log all signatures)
- human-readable identity (e.g. X.509 TLS Certificate)

# STAM

## signature details

- DC engineer signs (signed provisioning manifest)
- TPM signs (signed TPM measurements)
- Developer signs (signed code)
- Build chain signs (signed reproducible builds)
- Log, witnesses & TPM sign (measure a recent Sigsum STH)
- Log & witnesses sign (Sigsum log all signatures)
- Web CA signs (e.g. X.509 TLS Certificate)

# STAM

## signature details, cont.

- DC engineer signs : TPM event log during provisioning
- TPM signs : build artefacts in boot chain
- Developer signs : build artefacts
- Build chain signs : build artefacts, source code
- Log, witnesses & TPM sign : Sigsum STH
- Log & witnesses sign : all signatures mentioned
- Web CA signs : domain name

## TKey - (dev.tillitis.se)

- the most open-source hardware USB security key
- The TKey's schematic, PCB design, circuit design (Verilog) and software is open source. Enjoy!

## TKey - (dev.tillitis.se)

Core idea:

- based on the idea of measured boot using TCG DICE
- KDF: `blake2s(UDS, blake2s(device_app), USS)`
